Problem I<br>Internet Service Providers

Input File: I.IN
Output File: standard output
Program Source File: I.C, I.CPP, I.JAVA
A group of $\mathbf{N}$ Internet Service Provider companies (ISPs) use a private communication channel that has a maximum capacity of $\mathbf{C}$ traffic units per second. Each company transfers $\mathbf{T}$ traffic units per second through the channel and gets a profit that is directly proportional to the factor $\mathbf{T}(\mathbf{C}-\mathbf{T} \mathbf{N})$. The problem is to compute T_optim, the smallest value of $\mathbf{T}$ that maximizes the total profit the $\mathbf{N}$ ISPs can get from using the channel. Notice that $\mathbf{N}, \mathbf{C}, \mathbf{T}$, and $\mathbf{T}$ _optim are integer numbers.

Write a program that reads sets of data from an input text file. Each data set corresponds to an instance of the problem above and contains two integral numbers - $\mathbf{N}$ and $\mathbf{C}$ - with values in the range from 0 to $10^{9}$. The input data are separated by white spaces, are correct, and terminate with an end of file. For each data set the program computes the value of T_optim according to the problem instance that corresponds to the data set. The result is printed on the standard output from the beginning of a line. There must be no empty lines on the output. An example of input/output is shown below.

| Input |  |  |
| :--- | :--- | :--- |
| 1 | 0 | 0 |
| 0 | 1 | 0 |
| 4 | 3 | 0 |
| 2 | 8 | 2 |
| 3 | 27 | 4 |
| 25 | 1000000000 | 20000000 |
